

National Infrastructure Protection Center CyberNotes: 2001 Year End Summary

Issue #2001-26

December 31, 2001

CyberNotes is published every two weeks by the National Infrastructure Protection Center (NIPC). Its mission is to support security and information system professionals with timely information on cyber vulnerabilities, malicious scripts, information security trends, virus information, and other critical infrastructure-related best practices.

You are encouraged to share this publication with colleagues in the information and infrastructure protection field. Electronic copies are available on the NIPC web site at <http://www.nipc.gov>.

Please direct any inquiries regarding this publication to the Editor-CyberNotes, National Infrastructure Protection Center, FBI Building, Room 11719, 935 Pennsylvania Avenue, NW, Washington, D.C., 20535.

Bugs, Holes & Patches

The following table provides a year-end summary of software vulnerabilities identified between December 12, 2000 and December 14, 2001. The table provides the vendor, software name, operating system, common name of the vulnerability, potential risk at the time of publication, and the CyberNotes issue in which the vulnerability appeared. Software versions are identified if known. **This information is presented only as a summary; complete details are available from the source indicated in the endnote.** Please note that even if the method of attack has not been utilized or an exploit script is not currently widely available on the Internet, a potential vulnerability has been identified. **Updates to items appearing in previous issues of CyberNotes are listed in bold. New information contained in the update will appear in italicized colored text.** Where applicable, the table lists a "CVE number" (in red) which corresponds to the Common Vulnerabilities and Exposures (CVE) list, a compilation of standardized names for vulnerabilities and other information security exposures.

*“Risk” is defined by CyberNotes in the following manner:

High - A high-risk vulnerability is defined as one that will allow an intruder to immediately gain privileged access (e.g., sysadmin or root) to the system or allow an intruder to execute code or alter arbitrary system files. An example of a high-risk vulnerability is one that allows an unauthorized user to send a sequence of instructions to a machine and the machine responds with a command prompt with administrator privileges.

Medium – A medium-risk vulnerability is defined as one that will allow an intruder immediate access to a system with less than privileged access. Such vulnerability will allow the intruder the opportunity to continue the attempt to gain privileged access. An example of medium-risk vulnerability is a server configuration error that allows an intruder to capture the password file.

Low - A low-risk vulnerability is defined as one that will provide information to an intruder that could lead to further compromise attempts or a Denial of Service (DoS) attack. It should be noted that while the DoS attack is deemed low from a threat potential, the frequency of this type of attack is very high. DoS attacks against mission-critical nodes are not included in this rating and any attack of this nature should instead be considered to be a “High” threat.

Viruses

The following table provides the reader with a year-end summary of the top ten high threat viruses, as reported to various anti-virus vendors and virus incident reporting organizations. For the purposes of collecting and collating data, infections involving multiple systems at a single location are considered a single infection. It is therefore possible that a virus has infected hundreds of machines but has only been counted once. **To limit the possibility of infection, readers are reminded to update their anti-virus packages as soon as updates become available.** The table lists the viruses by ranking (number of sites affected), common virus name, type of virus code (i.e., boot, file, macro, multi-partite, script), trends (based on number of infections reported during the latest three months), and approximate date first found. During the year, a number of anti-virus vendors have included information on Trojan Horses and Worms. *NOTE: At times, Trojans may contain names or content that may be considered offensive.*

Ranking	Common Name	Type of Code	Date
1	W32/SirCam	Worm	July 2001
2	W32/Magistr-(A &B)	File, Worm	March 2001
3	W32/Hybris	File, Worm	November 2000
4	W32/Nimda	File, Worm	September 2001
5	W32/BadTrans	Worm	April 2001
6	W32/Goner	Worm	December 2001
7	W32/Apology (MTX)	File Infector, Trojan	September 2000
8	VBS/Homepage	Script	May 2001
9	VBS/SST (Anna K.)	Script, Worm	February 2001
10	W32/CodeRed	Worm	July 2001

Trojans

“Trojan Horse programs”, or Trojans, have become increasingly popular as a means of obtaining unauthorized access to computer systems. The increasing number of Trojans in 2001 gains added significance due to recent testing conducted to determine the ability of anti-virus software to detect Trojans. According to the test results, a number of popular anti-virus products failed to detect or had limited detection capabilities against current popular Trojans. Testing also indicates that detection of a baseline Trojan does not necessarily mean the anti-virus software can detect a variant. Readers should contact their anti-virus vendors to obtain specific information on Trojans and their variants that their software detects.

The following table provides the reader with a summary list of Trojans that have received write-ups in during the past year in CyberNotes. A version number is provided where relevant. *NOTE: At times, Trojans may contain names or content that may be considered offensive.*
